

Validation & Qualification of Space Debris Laser Systems at the Expert Centre for Space Safety

Julian Rodriguez-Villamizar, Thomas Schildknecht, Pierre Lauber

Astronomical Institute, University of Bern, Switzerland

22nd International Workshop on Laser Ranging
7-11 November
Yebeles, Spain

Agenda

- Problem Statement
- Observation Equation
- Example
- Road Map V & Q

Problem Statement

How can we determine the quality, performance and stability of a given space debris laser ranging system to ensure an optimal exploitation of the observable?

Rationale: Let's try to split the problem analyzing the error sources of the observable assessing their contribution **considering only single passes from a unique station.**

Observation Equation:

$$\rho_{obs}^{1-way}(t) = \|X^S(t) - X_R(t)\| + T(*)_{del} + S(*)_{del} + CoM(*) + Rel(*) + Rb(*) + \xi.$$

(*) → dependencies due to system, target, etc.

Problem Statement

How can we determine the quality, performance and stability of a given space debris laser ranging system to ensure an optimal exploitation of the observable?

Rationale: Let's try to split the problem analyzing the error sources of the observable assessing their contribution **considering only single passes from a unique station.**

Observation Equation:

$$\rho_{obs}^{1-way}(t) = ||X^S(t) - X_R(t)|| + T(*)_{del} + S(*)_{del} + CoM(*) + Rel(*) + Rb(*) + \xi.$$

(*) → dependencies due to system, target, etc.

Observation Equation

Satellite Position

How good are the orbits? On average ≈ 10 cm \rightarrow orbit misclosures

When no overlap \rightarrow extrapolated overlap if error ≤ 5 cm

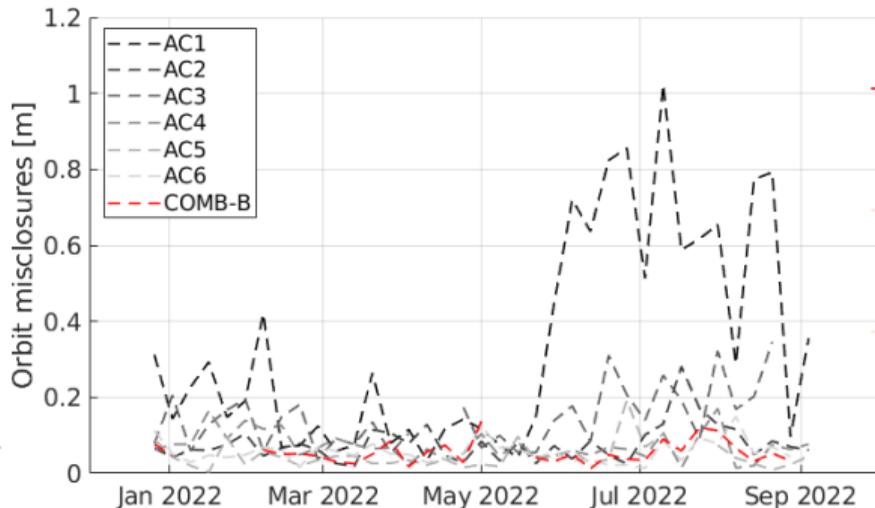

Could we use precise predictions instead?

Error between CPFs and COMB-B of about 10 cm at same epoch and ≈ 30 cm after 3 days

Orbit overlaps LAGEOS-1 7-arc solution \neq AC

Observation Equation

Satellite Position

— How good are the orbits? On average ≈ 10 cm \rightarrow orbit misclosures

— When no overlap \rightarrow extrapolated overlap if error ≤ 5 cm

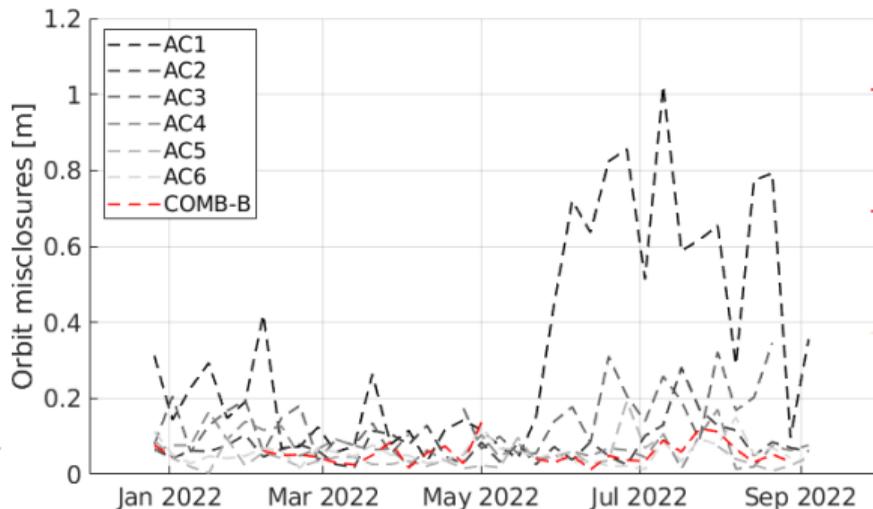

— Could we use precise predictions instead?

Observation Equation

Station Coordinates & Eccentricities

Coordinates estimated according to ILRS framework:

- Estimate station position, velocities & formal errors associated to a specific reference frame (ideally SLRF2020)
- Include corrections to the station coordinates (post-seismic deformations, tidal effects, etc.) when > 30 cm (predictions)

If sensor prefers to be agnostic to any existing network:

- Consistency with reference frame of the orbit?
- Quality of your coordinates \rightarrow as good as you tell us

Observation Equation

Observation Equation

Tropospheric Path Delay

- Yes, it is a must (models available Marini-Murray & Mendes-Pavlis)
- Dependent on the relative geometry of the observed pass, wavelength & meteorological information of the station

Observation Equation

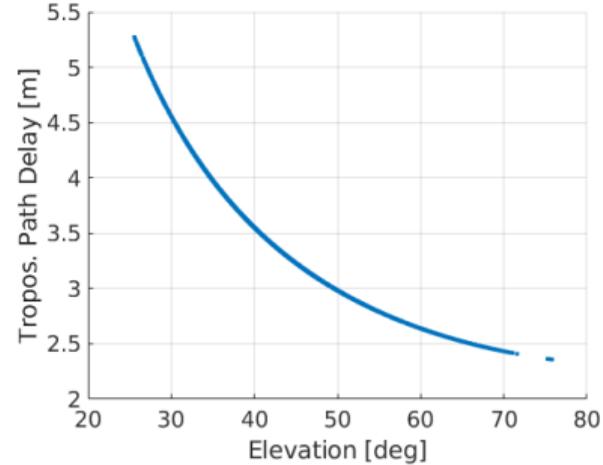

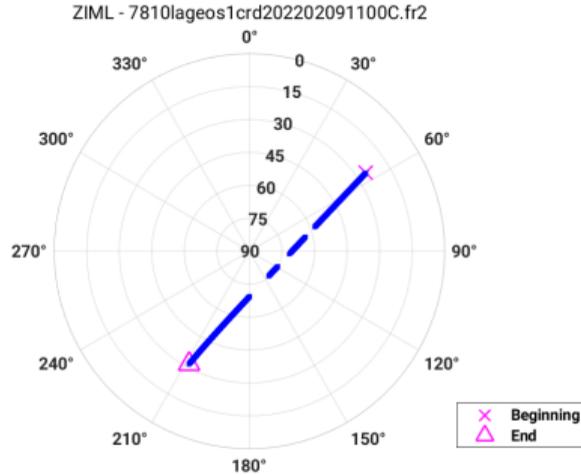

Tropospheric Path Delay

- Yes, it is a must (models available Marini-Murray & Mendes-Pavlis)
- Dependent on the relative geometry of the observed pass, wavelength & meteorological information of the station

Observation Equation

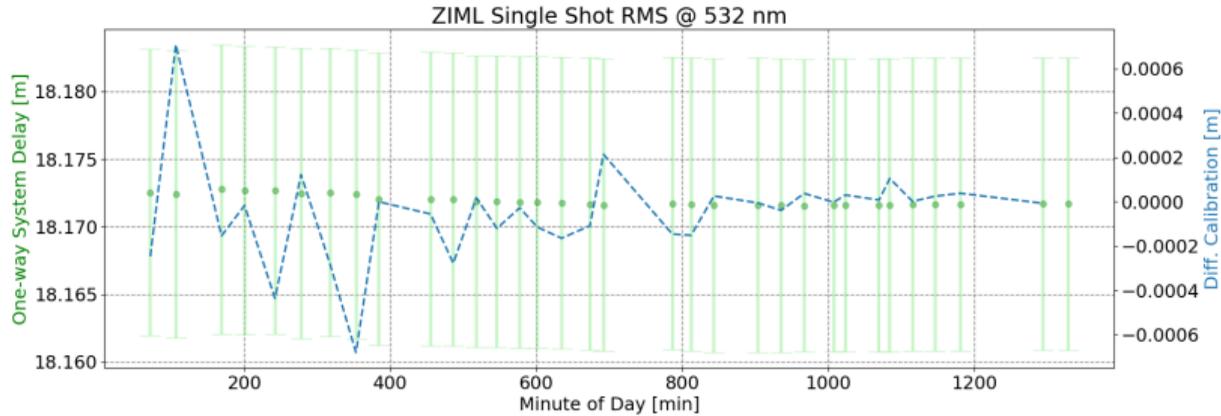

Tropospheric Path Delay

- Yes, it is a must (models available Marini-Murray & Mendes-Pavlis)
- Dependent on the relative geometry of the observed pass, wavelength & meteorological information of the station

Observation Equation

System Delays \longleftrightarrow Range Bias

- Agreement between the pulse width (60 psec @ 7810) and dispersion (error bars)
- Stability of the system delays over time
- Consider a longer time span analysis to have a more representative figure

Observation Equation

Center of Mass Correction

- Corrections dependent on target object & system specifications
- For fiducial targets CoM offsets are estimated for stations with technical specifications (see ILRS recommendations)

How to proceed with completely new sensors?

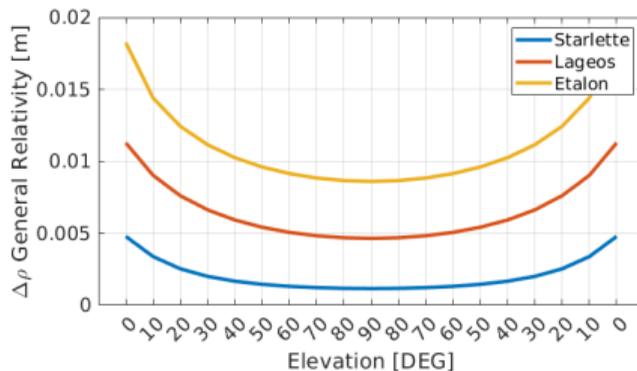

- Only relevant for validation
- For space debris laser systems, the *standard* CoM for LAGEOS-1 is 25.1 cm (!)

Observation Equation

Other Corrections: General Relativity (Light Path Bending)

$$|\text{certain corrections}| < |\epsilon X^s|$$

Example:

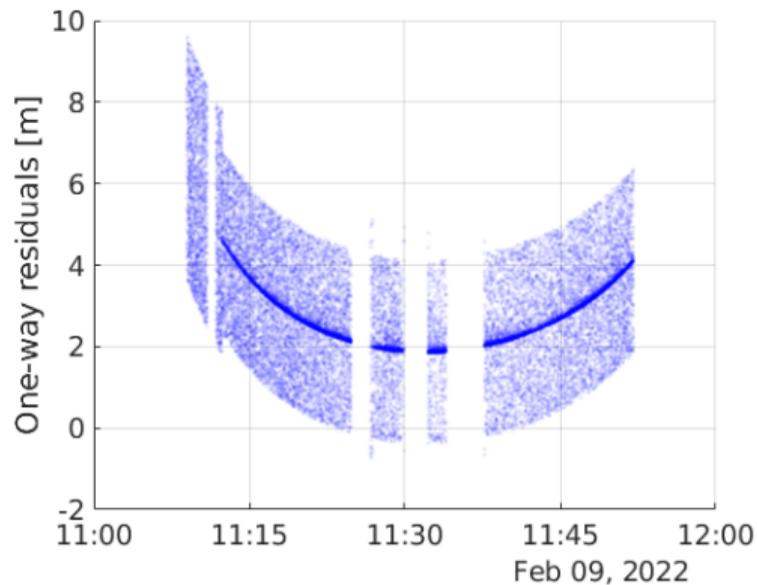

Other corrections applied for round trip travel time in ECEF:

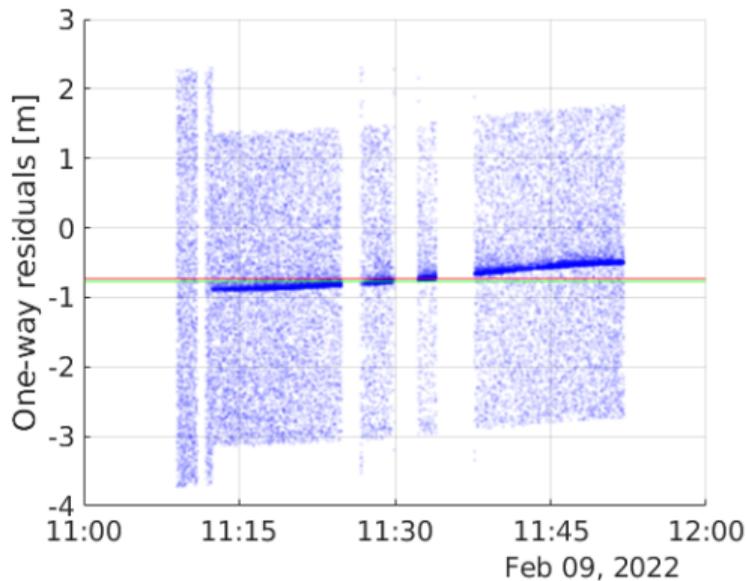

- Sagnac
- Light travel time

Example

Only from system delays

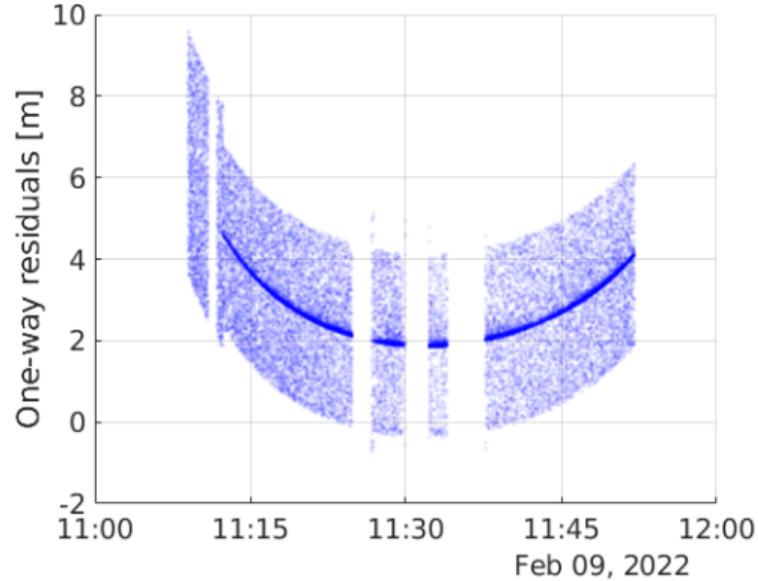

Other error sources

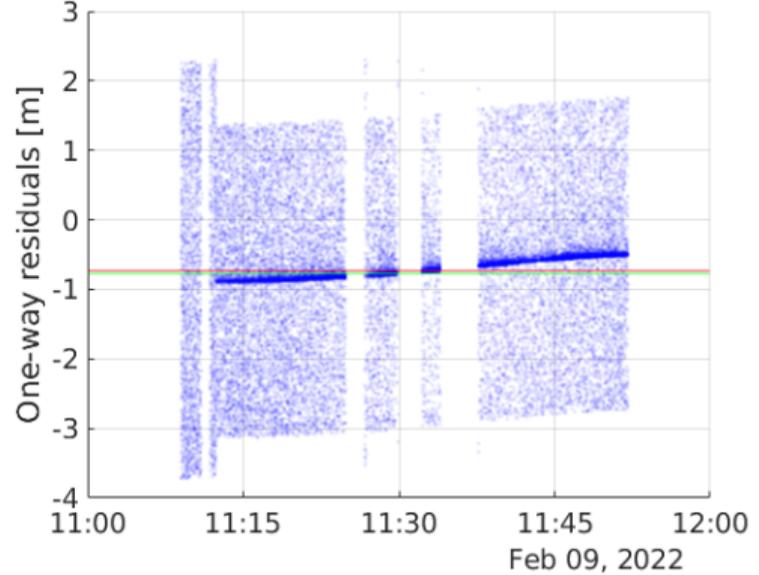

Visible trend of the residuals?

Example

Visible trend of the residuals?

Example

First order approximation:

- 1st order Taylor series expansion ($O(Tb^2)$) of ρ_{obs}^{1-way} yields:
Rb = -0.70 m \pm 0.02 m,
Tb = -0.10 msec \pm 0.01 msec.
- Remaining trend may be modeled by variations in $X^S(t)$ or $X_R(t)$

Consistency check:

Pass Num.	Tb [msec]	Rb [m]
Feb-09-22 11:00	-0.1	-0.70
Feb-09-22 15:00	-0.2	-0.60
Feb-09-22 23:00	-0.1	-0.50

Example
